1 Definitions

Definition 1.1. Let $X, X_n : \Omega \rightarrow \mathbb{R}$ be random variables ($n \in \mathbb{N}$) defined on the same probability space $(\Omega, \mathcal{A}, \mathbb{P})$. We say that

(i) $X_n \xrightarrow{\text{a.s.}} X$, X_n converges to X almost surely (a.s.) or $X_n \xrightarrow{n \uparrow \infty} X$ with probability one

$$:\Leftrightarrow \mathbb{P}\left(\omega \in \Omega : \lim_{n \rightarrow \infty} X_n(\omega) = X(\omega)\right) = 1.$$

▷ «presque sûrement» (p.s.), «fast sicher» (f.s.) or «avec probabilité 1», «mit Wahrscheinlichkeit 1».

(ii) $X_n \xrightarrow{\mathbb{P}} X$, X_n converges to X in probability or X_n converges stochastically to X

$$:\Leftrightarrow \forall \varepsilon > 0 : \lim_{n \rightarrow \infty} \mathbb{P}(|X_n - X| > \varepsilon) = 0$$

▷ en probabilité, in Wahrscheinlichkeit or -, stochastisch.

(iii) $X_n \xrightarrow{L^p} X$, X_n converges to X in L^p or X_n converges to X in the p^{th} mean

$$:\Leftrightarrow \forall X, X_n \in L^p(\mathbb{P}) : \lim_{n \rightarrow \infty} \|X_n - X\|_{L^p} = 0,$$

where, $\|X\|_{L^p}(\mathbb{P}) := (\mathbb{E}|X|^p)^{1/p}$, i.e.

$$:\Leftrightarrow \forall X, X_n \in L^p : \lim_{n \rightarrow \infty} \mathbb{E}|X_n - X|^p = 0.$$

▷ dans L^p , in L^p or en moyenne d'ordre p , im p -ten Mittel.

Definition 1.2. Let $X, X_n : \Omega \rightarrow \mathbb{R}$ be random variables ($n \in \mathbb{N}$) *not necessarily* defined on the same probability space. We say that

(i) $X_n \xrightarrow{d/\mathcal{L}} X$, X_n converges to X in distribution/law

$$:\Leftrightarrow \lim_{n \rightarrow \infty} F_n(x) = \lim_{n \rightarrow \infty} \mathbb{P}(X_n \leq x) = \mathbb{P}(X \leq x) = F(x)$$

for all points $x \in \mathbb{R}$, where F is continuous.

▷ en loi, in Verteilung.

(ii) $X_n \xrightarrow{d/w} X$, X_n converges to X weakly

$$:\Leftrightarrow \forall f \in C_b(\mathbb{R}) : \lim_{n \rightarrow \infty} \mathbb{E}f(X_n) = \mathbb{E}f(X). \quad (1.1)$$

▷ faible, schwach.

Remark 1.3. (1) Since the real random variables X_n, X do not have to be defined on the same probability space in the definition of weak convergence, we actually should emphasise the dependance by writing \mathbb{P}, \mathbb{P}^n and \mathbb{E}, \mathbb{E}^n respectively. It is a common convention to omit this dependance.

(2) As already indicated in the notation in Definition 1.2, (i) and (ii) are equivalent (\rightsquigarrow Portmanteau theorem). We can equivalently write (1.1) as

$$\forall f \in C_b(\mathbb{R}) : \lim_{n \rightarrow \infty} \int f(x) \mathbb{P}(X_n \in dx) = \int f(x) \mathbb{P}(X \in dx).$$

In functional analysis it is common to write $\lim_{n \rightarrow \infty} \langle f, \mathbb{P}_{X_n} \rangle = \langle f, \mathbb{P}_X \rangle$, where $\langle f, \mu \rangle = \int f d\mu$.

2 Implications

Theorem 2.1. Let $X, X_n : \Omega \rightarrow \mathbb{R}$ be random variables ($n \in \mathbb{N}$) and $1 \leq p \leq \infty$. Then

$$(a) X_n \xrightarrow{L^p} X \implies X_n \xrightarrow{L^1} X$$

$$(b) X_n \xrightarrow{L^1} X \implies X_n \xrightarrow{\mathbb{P}} X$$

$$(c) X_n \xrightarrow{\text{a.s.}} X \implies X_n \xrightarrow{\mathbb{P}} X$$

Proof. (a) Let $1 \leq p < \infty$ and q the conjugate exponent $1/p + 1/q = 1$. By Hölder's inequality

$$\begin{aligned} \mathbb{E} |X_n - X| &= \int |X_n - X| \cdot 1 \, d\mathbb{P} \leq \left(\int |X_n - X|^p \, d\mathbb{P} \right)^{1/p} \left(\int 1^q \, d\mathbb{P} \right)^{1/q} \\ &= (\mathbb{E} |X_n - X|^p)^{1/p} \xrightarrow[\text{assumption}]{n \uparrow \infty} 0. \end{aligned}$$

The case $p = \infty$ follows in a completely analogue matter. In particular, we have shown that $L^p(\mathbb{P}) \hookrightarrow L^1(\mathbb{P})$ is a continuous embedding.

(b) By the Chebyshev–Markov inequality, we get

$$\forall \varepsilon > 0 : \quad \mathbb{P}(|X_n - X| > \varepsilon) \leq \frac{1}{\varepsilon} \mathbb{E} |X_n - X| \xrightarrow{n \uparrow \infty} 0.$$

(c) For all $\varepsilon > 0$ we have

$$\mathbb{P}(|X_n - X| > \varepsilon) = \mathbb{E} \mathbb{1}_{\{|X_n - X| > \varepsilon\}} = \mathbb{E} \mathbb{1}_{[-\varepsilon, \varepsilon]^c}(X_n - X).$$

The random variables $Y_n := \mathbb{1}_{\{|X_n - X| > \varepsilon\}}$ are uniformly bounded by $\mathbf{1} \in L^p(\mathbb{P})$ and $Y_n \xrightarrow{n \uparrow \infty} 0$ a.s. Hence, by dominated convergence [A.1](#), it follows

$$\forall \varepsilon > 0 : \quad \mathbb{P}(|X_n - X| > \varepsilon) = \mathbb{E} \mathbb{1}_{\{|X_n - X| > \varepsilon\}} \xrightarrow{n \uparrow \infty} 0. \quad \blacksquare$$

Theorem 2.2. Let $X, X_n : \Omega \rightarrow \mathbb{R}$ be random variables ($n \in \mathbb{N}$) such that $X_n \xrightarrow{\mathbb{P}} X$. Then $X_n \xrightarrow{d} X$. Moreover, it holds $f(X_n) \xrightarrow{L^1} f(X)$ for all $f \in C_b(\mathbb{R})$.

Proof. Let $f \in C_b(\mathbb{R})$ and $\varepsilon > 0$ fixed. Since $\{|X| > k\} \downarrow \emptyset$ for $k \uparrow \infty$, by the \emptyset -continuity of the probability measure \mathbb{P} , we have

$$\exists N = N(\varepsilon) \in \mathbb{N} \, \forall k \geq N : \quad \mathbb{P}(|X| > k) < \varepsilon. \quad (2.1)$$

By assumption $|f| \leq M$, for some suitable constant M , and $f|_{[-(N+1), N+1]}$ is uniformly continuous, i.e.

$$\exists \delta = \delta(\varepsilon) \in (0, 1) \, \forall |x|, |y| \leq N + 1, |x - y| \leq \delta : \quad |f(x) - f(y)| \leq \varepsilon. \quad (2.2)$$

Hence, splitting the area of integration in clever way,

$$\begin{aligned} \mathbb{E} |f(X_n) - f(X)| &\leq \mathbb{E} |f(X_n) - f(X)| \\ &\leq \left(\int_{\{|X_n - X| \leq \delta\} \cap \{|X| \leq N\}} + \int_{\{|X_n - X| \leq \delta\} \cap \{|X| > N\}} + \int_{\{|X_n - X| > \delta\}} \right) |f(X_n) - f(X)| \, d\mathbb{P} \\ &\leq \underbrace{\varepsilon \mathbb{P}(|X_n - X| \leq \delta, |X| \leq N)}_{|X_n| \leq |X_n - X| + |X| \leq \delta + N \leq 1 + N} + \underbrace{2M \mathbb{P}(|X| > N) + 2M \mathbb{P}(|X_n - X| > \delta)}_{|f(x) - f(x)| \leq 2\|f\|_\infty \leq 2M} \end{aligned}$$

where we used that $|f| \leq M$ together with (2.2) and since on the set $\{|X_n - X| \leq \delta\} \cap \{|X| \leq N\}$, we have $|X_n| \leq |X_n - X| + |X| \leq \delta + N \leq 1 + N$. Finally, using (2.1), we get

$$\mathbb{E} |f(X_n) - f(X)| \leq (2M + 1)\varepsilon + 2M\mathbb{P}(|X_n - X| > \delta) \xrightarrow{n \uparrow \infty} (2M + 1)\varepsilon \xrightarrow{\varepsilon \downarrow 0} 0,$$

thus $f(X_n) \rightarrow f(X)$ in L^1 and $\mathbb{E}f(X_n) \rightarrow \mathbb{E}f(X)$. ■

3 «Subsequence» implications

Recall the definition of the limit superior of sets:

$$\omega \in \limsup A_n := \bigcap_{m \in \mathbb{N}} \left(\bigcup_{n \geq m} A_n \right) \iff \omega \text{ appears in infinitely many of the } A_n$$

Hence, we can justify the probabilistic terms

$$\limsup A_n = \{A_n \text{ for infinitely many } n \in \mathbb{N}\} = \{A_n \text{ infinitely often (i.o.)}\}.$$

Lemma 3.1 (Borel-Cantelli). *Let $(A_n)_{n \in \mathbb{N}} \subset \mathcal{A}$. Then*

$$\sum_{n \in \mathbb{N}} \mathbb{P}(A_n) < \infty \implies \mathbb{P}(A_n \text{ for infinitely many } n \in \mathbb{N}) = 0.$$

Proof.

$$\omega \in \limsup A_n \iff \omega \text{ appears in infinitely many of the } A_n \iff \sum_{n \in \mathbb{N}} \mathbb{1}_{A_n}(\omega) = \infty.$$

By Beppo Levi, it follows that

$$\mathbb{E} \left(\sum_{n \in \mathbb{N}} \mathbb{1}_{A_n}(\omega) \right) = \sum_{n \in \mathbb{N}} \mathbb{E} \mathbb{1}_{A_n}(\omega) = \sum_{n \in \mathbb{N}} \mathbb{P}(A_n) < \infty,$$

and we see that $\sum_{n \in \mathbb{N}} \mathbb{1}_{A_n}(\omega) < \infty$ a.s., hence $\mathbb{P}(A_n \text{ for infinitely many } n \in \mathbb{N}) = 0$. ■

Making the special choice $A_n := \{|X_n - X| > \varepsilon\}$ in 3.1, we can prove that having control of a fast rate of convergence of $\mathbb{P}(|X_n - X| > \varepsilon) \rightarrow 0$, we already get convergence almost surely.

Lemma 3.2. *Let $X, X_n : \Omega \rightarrow \mathbb{R}$ be random variables ($n \in \mathbb{N}$) with $X_n \xrightarrow{\mathbb{P}} X$ and a null sequence $\varepsilon_n \downarrow 0$ with $\mathbb{P}(|X_n - X| > \varepsilon_n) < \infty$. Then $X_n \xrightarrow{\text{a.s.}} X$.*

Proof. By the Borel-Cantelli lemma 3.1,

$$\begin{aligned} \mathbb{P}(A_n \text{ for infinitely many } n \in \mathbb{N}) &= 0 \\ \iff \mathbb{P}(A_n \text{ for at most finitely many } n \in \mathbb{N}) &= 1 \\ \iff \exists \Omega' \subset \Omega, \mathbb{P}(\Omega') = 1 \quad \forall \omega \in \Omega' \exists N(\omega) \forall n \geq N(\omega) : & |X_n(\omega) - X(\omega)| < \varepsilon_n \\ \implies \forall \omega \in \Omega' : |X_n(\omega) - X(\omega)| \xrightarrow{n \uparrow \infty} 0. & \end{aligned}$$

Corollary 3.3 (\mathbb{P} convergence \implies a.s. of subsequence). *Let $X, X_n : \Omega \rightarrow \mathbb{R}$ be random variables ($n \in \mathbb{N}$). Then*

$$X_n \xrightarrow{\mathbb{P}} X \implies \exists (X_{n(k)})_{k \in \mathbb{N}} : X_{n(k)} \xrightarrow[\text{a.s.}]{k \uparrow \infty} X.$$

Proof. By assumption,

$$\forall k \in \mathbb{N} \forall \varepsilon > 0 \exists N(k, \varepsilon) \in \mathbb{N} \forall n \geq N(k, \varepsilon) : \mathbb{P}(|X_k - X| > \varepsilon) \leq 2^{-k}.$$

Choose $\varepsilon = 2^{-k}$ and $n(k) := N(k, 2^{-k})$. Hence,

$$\sum_{k \in \mathbb{N}} \mathbb{P}(|X_{n(k)} - X| > 2^{-k}) \leq \sum_{k \in \mathbb{N}} 2^{-k} < \infty.$$

and the assertion follows from Lemma 3.2. ■

Finally, we show a relation between convergence in distribution and convergence in probability.

Lemma 3.4. *Let $X, X_n : \Omega \rightarrow \mathbb{R}$ be random variables ($n \in \mathbb{N}$) defined on the same probability space. If $X \equiv c$ is constant a.s., then*

$$X_n \xrightarrow{\mathbb{P}} X \equiv c \iff X_n \xrightarrow{d} X \equiv c.$$

Proof. \implies Clearly by 2.1.

\impliedby We choose a cut-off function in a clever way: Fix $\varepsilon > 0$ and $\chi_\varepsilon \in C_b(\mathbb{R})$ with $\chi_\varepsilon(0) = 0$ and $\chi_\varepsilon \geq \mathbb{1}_{[-\varepsilon, \varepsilon]^c}$. Then $\chi_\varepsilon(\cdot - c) \in C_c(\mathbb{R})$ and we have

$$\mathbb{P}(|X_n - X| > \varepsilon) \leq \int \chi_\varepsilon(X_n - X) d\mathbb{P} = \int \chi_\varepsilon(X_n - c) d\mathbb{P} \xrightarrow[n \uparrow \infty]{w} \int \chi_\varepsilon(X - c) d\mathbb{P} = 0. \quad \blacksquare$$

4 Counterexamples

Example 4.1. Let $(\Omega, \mathcal{A}, \mathbb{P}) = ([0, 1), \mathcal{B}[0, 1), \text{Leb}|_{[0,1)} = d\omega)$.

(a) L^1 -convergence $\not\Rightarrow L^p$ -convergence ($p > 1$)

$$X_n(\omega) = \mathbb{1}_{[1/n, 1)}(\omega) \omega^{-1/p}, \quad X(\omega) = \omega^{-1/p}.$$

(b) L^1 -convergence $\not\Rightarrow$ a.s. convergence

$$X_{n,k}(\omega) = \mathbb{1}_{[k/n, (k+1)/n)}(\omega), \quad n \in \mathbb{N}, k = 0, 1, \dots, n-1.$$

It is easy to see that $X(\omega) \equiv 0$ in L^1 , but the sequence does not converge at any point $\omega \in [0, 1)$.

(c) \mathbb{P} -convergence $\not\Rightarrow L^1$ -convergence

$$X_n(\omega) = n \mathbb{1}_{[0, 1/n)}(\omega), \quad X_n(\omega) \equiv 0.$$

(d) \mathbb{P} -convergence $\not\Rightarrow$ a.s. convergence. Clear by part (b).

(e) w -convergence $\not\Rightarrow \mathbb{P}$ -convergence (also if all random variables are defined on the same probability space). We define the so called «Rademacher» functions R_1, R_2, R_3, \dots by $R_n \sim \frac{1}{2}\delta_1 + \frac{1}{2}\delta_{-1}$, i.e. the R_n are defined alternating on sets of the same length. Clearly, $\mathbb{E}f(R_n) = \frac{1}{2}f(1) + \frac{1}{2}f(-1) \longrightarrow \mathbb{E}f(R_1)$, i.e. $R_n \xrightarrow{w} R_1$. On the other hand we see that the $R_n(\omega)$ cannot converge a.s., since

$$\liminf_{n \rightarrow \infty} R_n(\omega) = -1 < +1 = \limsup_{n \rightarrow \infty} R_n(\omega) \quad \forall \omega \in (0, 1).$$

For symmetry reasons we also have that, for $k \neq n$,

$$R_n - R_k = \begin{cases} 0, & \{R_n = R_k\} & \text{in } \frac{1}{2} \text{ of all cases} \\ +2, & \{R_n = 1, R_k = -1\} & \text{in } \frac{1}{4} \text{ of all cases} \\ -2, & \{R_n = -1, R_k = 1\} & \text{in } \frac{1}{4} \text{ of all cases.} \end{cases}$$

Hence, it follows that $\mathbb{P}(|R_n - R_k| > \varepsilon) = \frac{1}{2}$ for all $\varepsilon < 2$. So, $(R_n)_{n \in \mathbb{N}}$ cannot be a \mathbb{P} -Cauchy sequence, and thus, also not stochastically convergent.

A Appendix - some measure theory

Let E be a polish space, typically $E = \mathbb{R}, \mathbb{R}^n$, and (E, \mathcal{A}, μ) a measure space. Let $1 \leq p < \infty$. Recall that the spaces of p -times integrable functions are defined as

$$\mathcal{L}^p(E, \mathcal{A}, \mu) := \left\{ u : E \rightarrow \mathbb{R} : u \text{ measurable, } \int |u|(x)^p \mu(dx) < \infty \right\}, \quad (1 \leq p < \infty)$$

$$\mathcal{L}^\infty(E, \mathcal{A}, \mu) := \left\{ u : E \rightarrow \mathbb{R} : u \text{ measurable, } \exists c \geq 0, \mu\{|u| \geq c\} = 0 \right\}. \quad (p = \infty)$$

Moreover, we define the norms $u \mapsto \|u\|_{L^p}$ ($1 \leq p \leq \infty$)¹

$$\|u\|_{L^p} := \left(\int |u(x)|^p \mu(dx) \right)^{1/p}, \quad (1 \leq p < \infty)$$

$$\|u\|_\infty := \inf \{ c \geq 0, \mu\{|u| \geq c\} = 0 \}. \quad (p = \infty)$$

$\mathcal{L}^p(\mu)$ is a quasi-normed vector space, since only $\|u\|_{L^p} \iff u = 0$ a.e. and not necessarily $u \equiv 0$. But we can make $\mathcal{L}^p \rightsquigarrow L^p$ to a normed space by a standard procedure:

- Define an equivalence relation by: $u, v \in \mathcal{L}^p(\mu), u \sim v : \iff \mu(u \neq v) = 0$.
- Let $[u] := \{v \in \mathcal{L}^p(\mu) : v \sim u\}$ the equivalence relation with representative u .
- Then $\|[u]\|_{L^p} := \inf \{ \|v\|_{L^p} : v \in [u] \} = \|u\|_{L^p}$ ($u = v$ a.e.!).
- Define $L^p(\mu) := \mathcal{L}^p(\mu) / \sim \equiv \{ [u] : u \in \mathcal{L}^p(\mu) \}$.

Then $L^p(\mu)$ is a vector space with (true) norm $\|[u]\|_{L^p}$.

Caution

- One normally speaks of L^p -functions, where we just identify every $[u]$ with a «good» representative $u_0 \in [u]$. This is justified since $[u] = [u_0]$ ($u_0 \in [u]$) and hence every representative is unique only up to a null set.
- Expressions like $u = v, u \leq v$ are understood only up to null sets, i.e. $u = v$ a.e., $u \leq v$ a.e. etc.
- $u \in \mathcal{L}^p(\mu) \iff u$ measurable and $|u|^p \in L^1(\mu)$.

Next, we state the **Dominated convergence theorem** or **Theorem of Lebesgue**. Its power and flexibility is one of the primary advantages of Lebesgue's integration theory over Riemmanian. It is heavily used in probability theory to prove the convergence of the expectation of random variables.

Theorem A.1 (Dominated convergence, Lebesgue). *Let $(u_n)_{n \in \mathbb{N}} \subset \mathcal{L}^p(\mu), 1 \leq p < \infty$, be a sequence of real-valued measurable functions on (E, \mathcal{A}, μ) with*

¹To be precise, $u \mapsto \|u\|_{L^p}$ ($1 \leq p \leq \infty$) behaves almost like a norm, since we only have $\|u\|_{L^p} \iff u = 0$ a.e.

- $u_n(x) \xrightarrow{n \uparrow \infty} u(x)$ for μ -almost all x ,
- $|u(x)| \leq w$ for μ -almost all x and some positive $w \in \mathcal{L}^p(\mu)$ ($n \in \mathbb{N}$).

Then $u \in \mathcal{L}^p(\mu)$ and it holds

- (a) $\|u - u_n\|_{L^p} \xrightarrow{n \uparrow \infty} 0$,
- (b) $\|u_n\|_{L^p} \xrightarrow{n \uparrow \infty} \|u\|_{L^p}$.

Mind that

$$\text{Convergence in } L^p \lim_{n \rightarrow \infty} \|u - u_n\|_{L^p} \neq \text{Convergence of } L^p\text{-norms } \lim_{n \rightarrow \infty} \|u_n\|_{L^p} = \lim_{n \rightarrow \infty} \|u\|_{L^p}$$

This is reflected in the following theorem.

Theorem A.2 (Riesz). Let $(u_n)_{n \in \mathbb{N}} \subset \mathcal{L}^p(\mu)$, $1 \leq p < \infty$. If $u_n(x) \xrightarrow{n \uparrow \infty} u(x)$ μ -a.e. and $u \in \mathcal{L}^p(\mu)$, then:

$$\lim_{n \rightarrow \infty} \|u - u_n\|_{L^p} = 0 \iff \lim_{n \rightarrow \infty} \|u_n\|_{L^p} = \lim_{n \rightarrow \infty} \|u\|_{L^p}$$

Proof. \implies Δ -inequality backwards.

$$\iff \text{Using } |u - u_n|^p \leq 2^p (|u_n|^p + |u|^p) \text{ \& Fatou's lemma for } 2^p (|u_n|^p + |u|^p) - |u - u_n|^p \geq 0. \quad \blacksquare$$

Theorem A.3 (Riesz-Fischer). $\mathcal{L}^p(\mu)$, $1 \leq p < \infty$, is complete, i.e. every Cauchy sequence $(u_n)_{n \in \mathbb{N}} \subset \mathcal{L}^p(\mu)$ converges to some $u \in \mathcal{L}^p(\mu)$.

Corollary A.4. Let $(u_n)_{n \in \mathbb{N}} \subset \mathcal{L}^p(\mu)$, $1 \leq p \leq \infty$ with $u_n \xrightarrow{L^p} u$, then there exists a subsequence $(u_{n(k)})_{k \in \mathbb{N}}$ such that $u_{n(k)} \xrightarrow{n \uparrow \infty} u$ for almost all x .

Limits in measure on a non- σ -finite measure space (E, \mathcal{A}, μ) need not be unique, but in probability we only work with finite measures of mass one. Vitali's theorem generalises Lebesgue's dominated convergence theorem.

Theorem A.5 (Vitali's theorem). For $1 \leq p < \infty$, let $(X_n)_{n \in \mathbb{N}} \subset L^p(\mathbb{P})$ a sequence of random variables with $X_n \xrightarrow{\mathbb{P}} X$. Then for all equivalent:

- (i) $X_n \xrightarrow{L^p} X$
- (ii) $(|X_n|^p)_{n \in \mathbb{N}}$ is uniformly integrable
- (iii) $\mathbb{E} |X_n|^p \xrightarrow{n \uparrow \infty} \mathbb{E} |X|^p$

Remark A.6. Vitali's theorem A.5 still holds for measure spaces (X, \mathcal{A}, μ) which are not σ -finite. In this case, we can no longer identify the L^p -limit and the theorem reads: If $X_j \xrightarrow{w} X$ (measurable function enough), then the following are equivalent:

- (i) $(X_n)_{n \in \mathbb{N}}$ converges in L^p .
- (ii) $(X_n)_{n \in \mathbb{N}}$ is uniformly integrable.

(iii) $(\|X_n\|_p)_{n \in \mathbb{N}}$ converges in \mathbb{R} .
